Declaration of Interest

We, the authors, have no potential conflict of interests and nothing to disclose.

Take home messages

- Suboptimal Health Status is the physical state between health and disease, and is considered a reversible stage of pre-chronic disease.
- The Suboptimal Health Status questionnaire (SHSQ-25) is a reliable tool to detect suboptimal health.
- Assessment of Suboptimal Health Status, via the SHSQ-25, predicts the risk of developing chronic diseases, providing health professionals with a unique window of opportunity for early interventions prior to disease onset.

Health

“A state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity”.

World Health Organization

Suboptimal health status (SHS) is the physical state between health and disease

Ideal health

High risk
(Suboptimal Health Status)

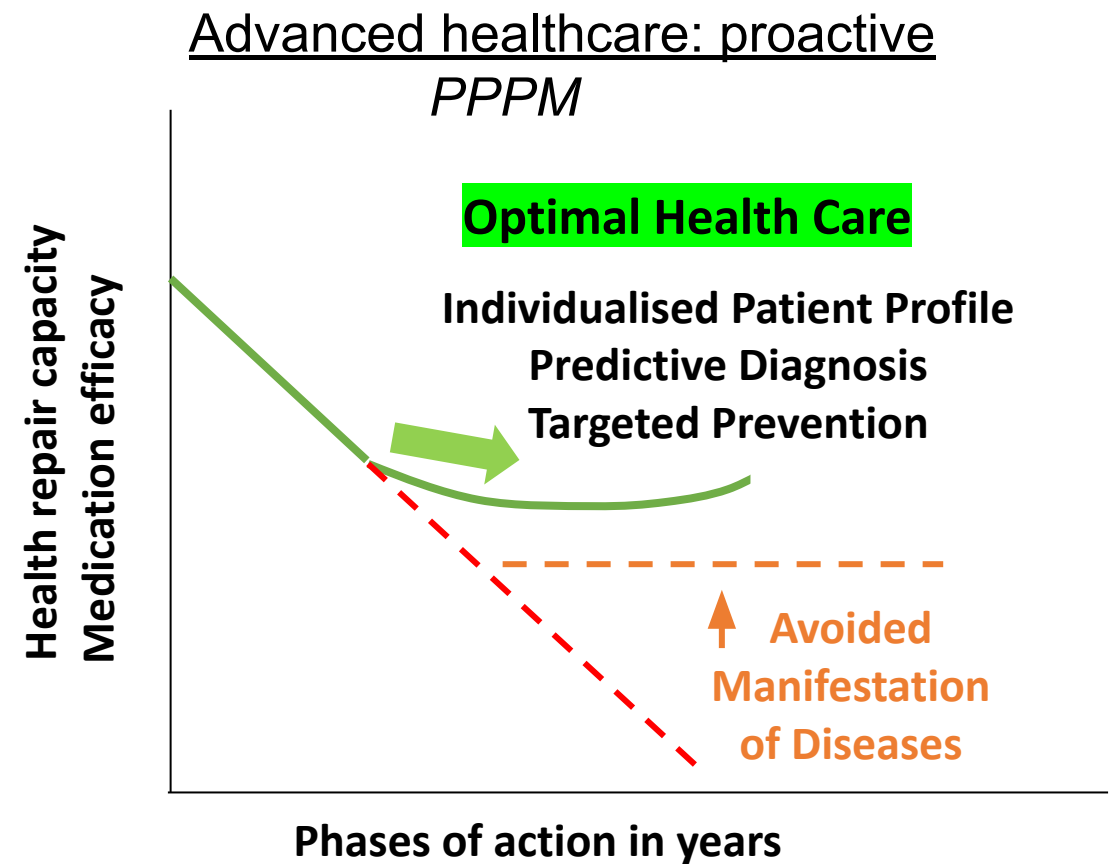

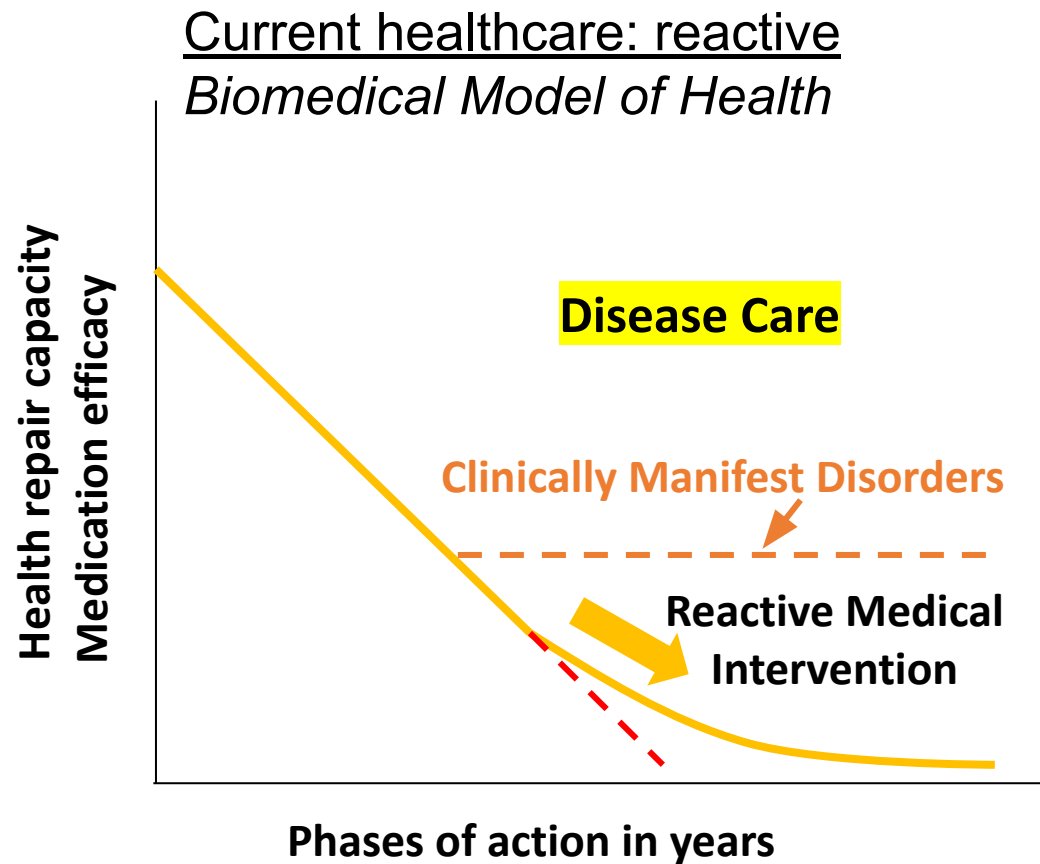

PATENTED

Chronic Diseases

Suboptimal Health provides a unique window of opportunity to prevent chronic disease

Research has identified stress as a key factor contributing to suboptimal health.

Pathophysiological response:

Neuroendocrine responses activated by the Hypothalamic- Pituitary-Adrenal (HPA)

Chronic stress: processes become maladaptive and can lead to disease

- Direct pathway: Effects of cortisol, CRP, IL-6
- Indirect pathway: Unhealthy diet, physical activity, alcohol and tobacco use

SHSQ-25

Measures health across 5 domains
using 25 items

F1 – Fatigue

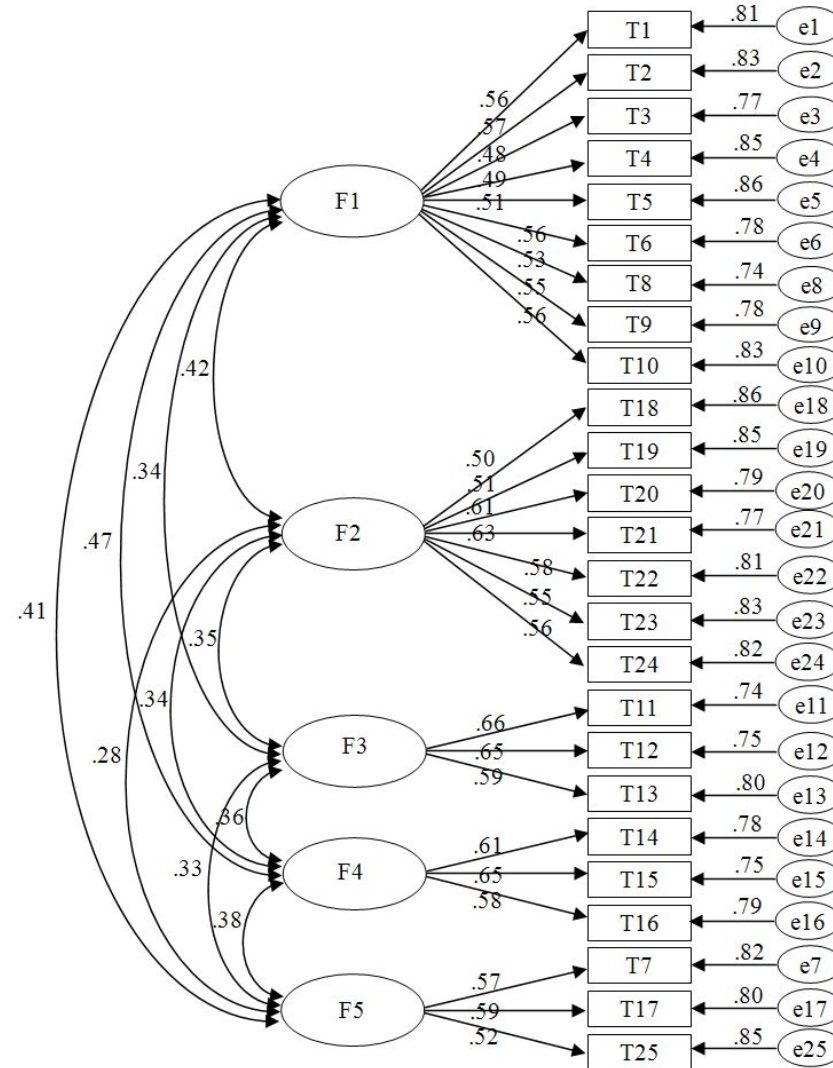

F2 – Mental

F3 – Cardiovascular

F4 – Digestive

F5 – Immune

- Total score summed (high/low score)
- High score = SHS
- Low score = Good health
- Able to distinguish between people with optimal health and suboptimal health

Confirmatory Factor Analysis (CFA)

χ^2	1324.818
Df	478
χ^2 / Df	2.772
GFI	0.915
AGFI	0.900

The High Maternal Death Rate in Resource-Limited Countries Could Be Reduced With a Simple Questionnaire

Date: 19/02/2019

Topic: [Pre-eclampsia](#)

ANAKEM, GATE – Researchers presented today at the 71st AACCC Annual Scientific Meeting & Clinical Lab Expo that a questionnaire-based algorithm could reduce the risk of a pregnant woman developing pre-eclampsia, a high maternal death rate in resource-limited countries by identifying women who need treatment for this often fatal condition.

Pre-eclampsia is a multisystem disorder that can cause devastating complications for mothers and babies. It is one of the leading causes of maternal-fetal mortality worldwide, and it disproportionately affects women in resource-limited countries. While pre-eclampsia is fatal for only 1 out of every million births in the U.K., it is responsible for more than 570 deaths per million births in Ghana. At present, it is considered an average pre-eclampsia death rate for low- and middle-income countries.

Pre-eclampsia often kills because healthcare providers aren't able to monitor pregnant women for its onset. To address this, a research team led by Enoch Anto, a PhD candidate at Edith Cowan University in Perth, Australia, created a simple, low-cost algorithm that identifies pregnant women who are at risk for pre-eclampsia. A key component of the algorithm is the Suboptimal Health Status Questionnaire (SHSQ-25), which assesses a patient's overall health status.

The Suboptimal Health Status Questionnaire was developed in 2009 by Professor Wei Wang from ECU's School of Health and Medical Sciences. Combining scores for fatigue, heart health, digestion, immunity and mental health, the questionnaire provides an overall 'suboptimal health score' that can help predict chronic diseases.

Professor Wang's PhD candidate Enoch Anto found that 61 per cent of women who scored high on the questionnaire went on to develop pre-eclampsia, compared with just 17 per cent of women who scored low.

When these results were combined with blood tests that measured women's calcium and magnesium levels, the researchers were able to accurately predict the development of pre-eclampsia in almost 80 per cent of cases.

Mr Anto said pre-eclampsia was very treatable once identified, so providing an early warning

Questionnaire-based algorithm predicts pre-eclampsia risk in pregnant women

Questionnaire-based algorithm predicts pre-eclampsia risk in pregnant women

Reviewed by James Lewis, PhD, Psychology

Research presented today at the 71st AACCC Annual Scientific Meeting & Clinical Lab Expo shows that a questionnaire-based algorithm predicts the risk of a pregnant woman developing pre-eclampsia, a high maternal death rate in resource-limited countries by identifying women who need treatment for this often fatal condition.

Pre-eclampsia is a multisystem disorder that can cause devastating complications for mothers and babies, from brain and liver injury in mothers to premature birth. It is one of the top causes of maternal-fetal mortality worldwide, and it disproportionately affects women in resource-limited countries. While pre-eclampsia is fatal for only 1 out of every million births in the U.K., it is responsible for more than 570 deaths per million births in Ghana. At present, it is considered an average pre-eclampsia death rate for low- and middle-income countries.

Pre-eclampsia often kills because healthcare providers aren't able to monitor pregnant women for its onset. To address this, a research team led by Enoch Anto, a PhD candidate at Edith Cowan University in Perth, Australia, created a simple, low-cost algorithm that identifies pregnant women who are at risk for pre-eclampsia. A key component of the algorithm is the Suboptimal Health Status Questionnaire (SHSQ-25), which assesses a patient's overall health status.

Simple test predicts dangerous pregnancy disorder | EurekAlert! Science News

Simple test predicts dangerous pregnancy disorder

Edith Cowan University

Australian researchers have developed a simple, low-cost way to predict pre-eclampsia, a potentially deadly condition that kills 76,000 mothers and 500,000 babies every year. The new test is based on a questionnaire that identifies pregnant women who are at risk for pre-eclampsia.

Pre-eclampsia can cause devastating complications for women and babies, including brain and liver injury in mothers and premature birth.

Pre-eclampsia can cause devastating complications for women and babies, including brain and liver injury in mothers and premature birth.

Survey gives early warning

ECU researchers assessed the health status of 593 pregnant Ghanaian women using the Suboptimal Health Questionnaire.

The Suboptimal Health Questionnaire was developed in 2009 by Professor Wei Wang from ECU's School of Health and Medical Sciences. Combining scores for fatigue, heart health, digestion, immunity and mental health, the questionnaire provides an overall 'suboptimal health score' that can help predict chronic diseases.

Professor Wang's PhD candidate Enoch Anto found that 61 per cent of women who scored high on the questionnaire went on to develop pre-eclampsia, compared with just 17 per cent of women who scored low.

When these results were combined with blood tests that measured women's calcium and magnesium levels, the researchers were able to accurately predict the development of pre-eclampsia in almost 80 per cent of cases.

Mr Anto said pre-eclampsia was very treatable once identified, so providing an early warning

Affordable method predicts dangerous pregnancy complication

Affordable method predicts dangerous pregnancy complication - The Week

Edith Cowan University

Australian researchers have developed a simple, low-cost method to predict pre-eclampsia, a potentially dangerous pregnancy complication characterised by high blood pressure.

Pre-eclampsia is a pregnancy complication that causes premature birth, and brain and liver injury in mothers, killing nearly half a million babies each year, globally. The study, published in the *BMJ* journal, noted that in developing nations, pre-eclampsia is a leading cause of death for both mothers and babies.

The researchers, including three from the Edith Cowan University (ECU) in Australia, assessed the health status of 593 pregnant Ghanaian women using the Suboptimal Health Status Questionnaire developed in 2009.

The questionnaire, the researchers said, combines participants' scores for fatigue, heart health, digestion, immunity and mental health, to generate an overall 'suboptimal health score' to predict chronic diseases.

They found that 61 per cent of women who scored high on the questionnaire went on to develop pre-eclampsia, compared to just 17 per cent of women who scored low.

When these results were combined with blood tests that measured women's calcium and magnesium levels, the researchers were able to accurately predict the development of pre-eclampsia in almost 80 per cent of cases.

Welcome

The COACS (China Sub-optimal Health Cohort Study) Study is a population-based, prospective, long-term follow-up cohort study. The study had two phases, cross-sectional and longitudinal. In the first cross-sectional phase, A total of over 9000 eligible participants had undergone an extensive clinical, laboratory and environmental exposure measurements protocol and aimed to identify clinical, biological, environmental and genetic associated factors. In the second phase, a long-term clinical follow-up is being performed with the purpose of better understanding environmental and genetic risk factors for ischemic events.

Our Research

BPMRI's medical and population health research aims for a better understanding and management of disease and illness. The institute's research activities are diverse and encompass a wide range of health conditions and measures. Our areas of study include sleep disorders, respiratory diseases, cardiovascular diseases, diabetes, genetics and others.

Yan et al, J Epidemiol, 2009

Carers are people who provide unpaid care and support to family members and friends who have a disability, mental illness, chronic condition, terminal illness, an alcohol or other drug issue or who are frail aged.

Carers are a disadvantaged group in society

- Experience significant burden
- Caring is an International issue
 - 2.7 million Australians affected
 - Total replacement cost \$60 billion
- Primary carers
 - Provide majority of care
 - 90% female
 - Sub-groups of carers (such as mothers whose child has a rare disease).

Psychological conditions

- Depression
- Anxiety
- High psychological distress

Physical conditions

- Impaired immune function
- Hyperglycaemia
- Hyperlipidaemia
- Cardiovascular disease
- Shortened life-span (telomere)

Aim: To understand the association between SHS and informal caring.

Study design: Observational, cross-sectional study (self-reported online survey)

Participants: Carers (n=170) and general population (n=170), female or male, aged between 18-75, able to speak English, and live in Australia.

Recruitment: Carer support groups, charity organisations, rare disease support groups, Facebook community groups and snowballing methods.

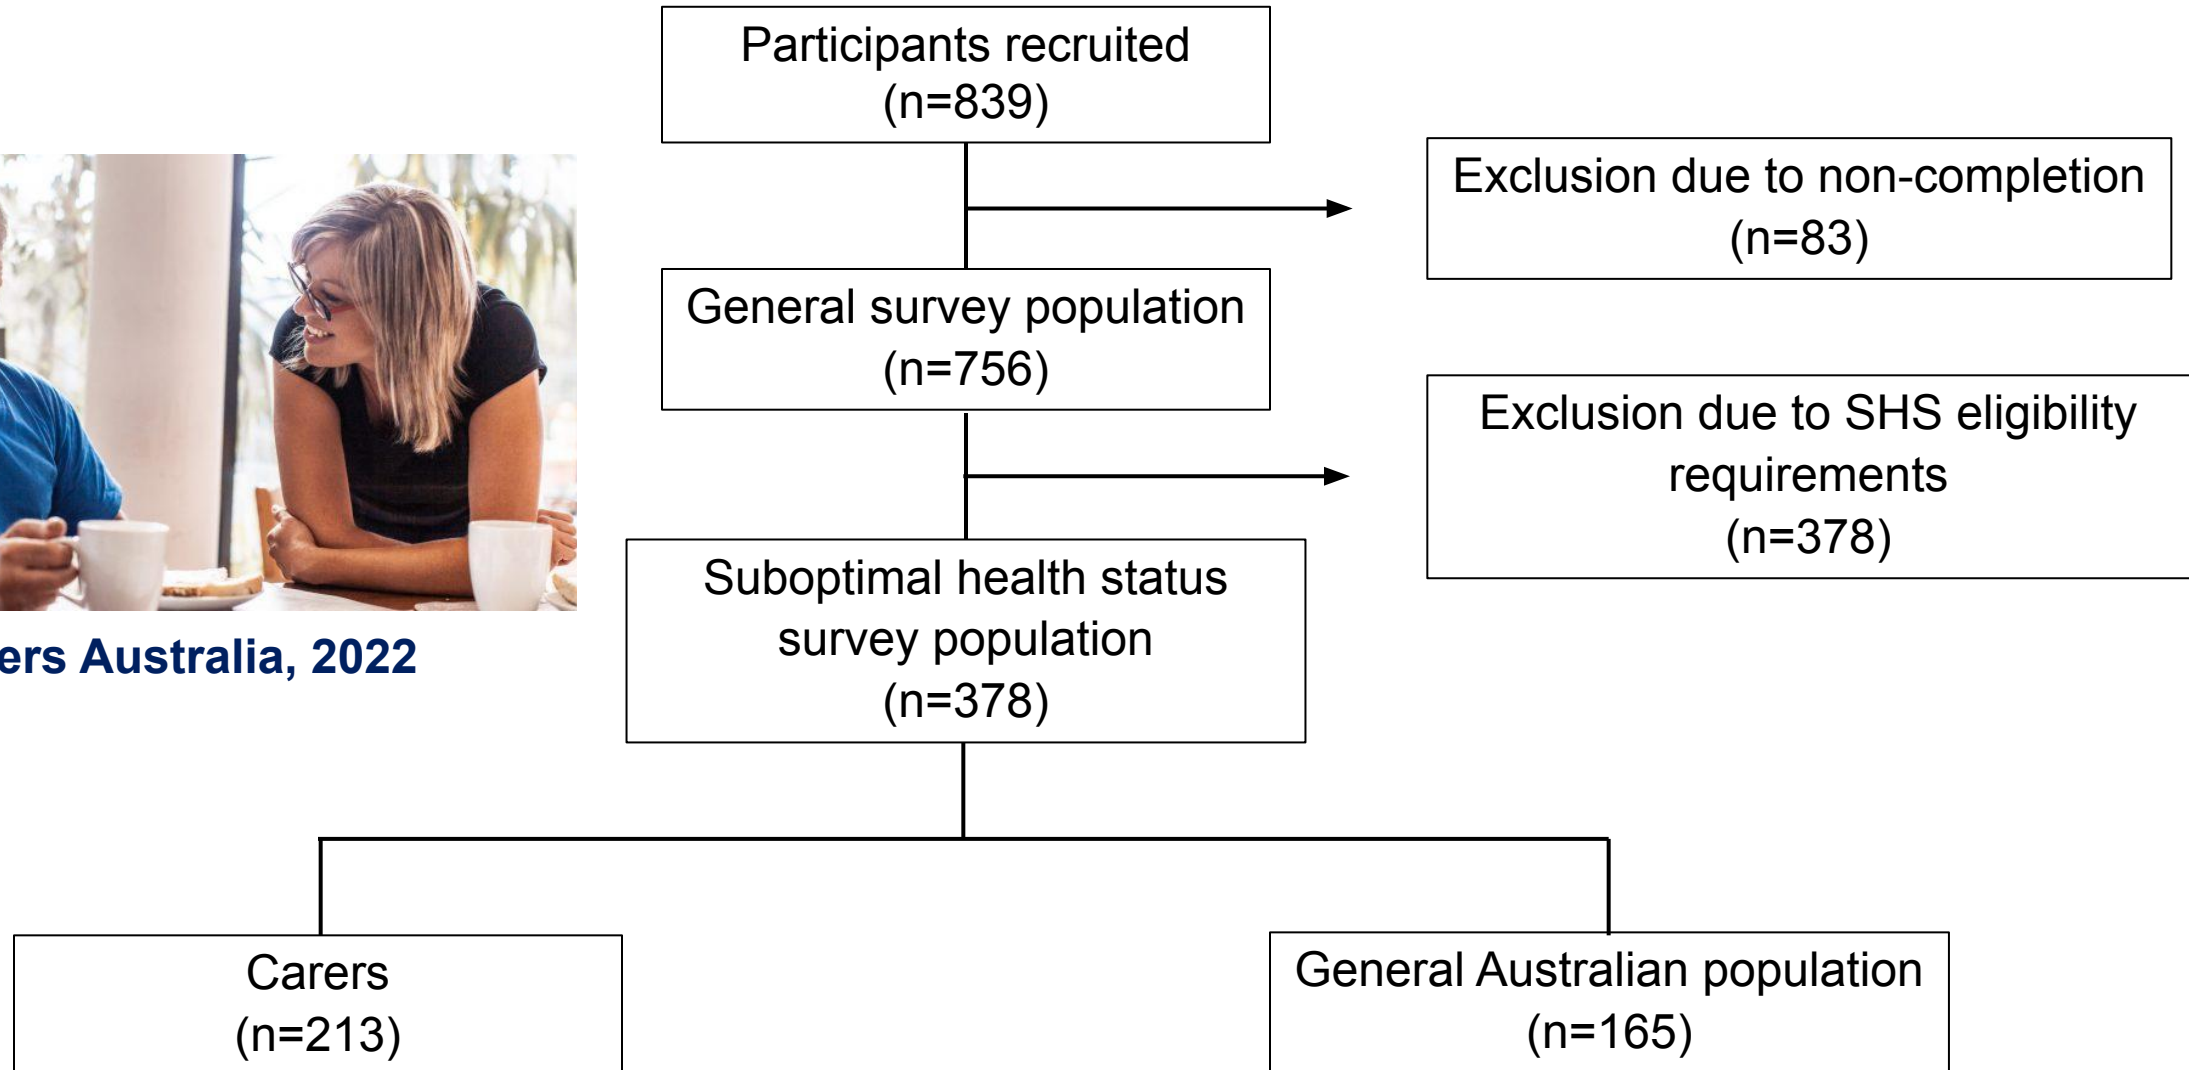

Primary measures: SHSQ-25

Secondary measures: DASS-21; Carer burden; sociodemographic.

The Association of Suboptimal Health Status and Caregiving in Australian Carers

Carers Australia, 2022

Research question

Are elevated levels of prolonged grief disorder, depression, and post-traumatic stress disorder associated with SHS in bereaved mothers?

Aim: To understand the association between prolonged grief disorder, depression, and post-traumatic stress disorder with SHS in bereaved parents.

Study design: Observational, cross-sectional study (self-reported online survey)

Participants: Mothers and fathers (n=132), aged between 18-70, able to speak English, live in Australia, who child died in the last 5 years.

Recruitment: Grief community groups, snowballing methods.

Primary measures: Suboptimal health status (SHSQ-25)

Secondary measures: Depression, anxiety, and stress (DASS-21); Prolonged grief (PG-13); Post-traumatic stress disorder (PCL-5); sociodemographic data.
